ABSTRACT

La₂O₂CO₃, CeO₂, ZrO₂, and Al₂O₃ supported Ni catalysts were prepared by an impregnation method and employed for reforming of *n*-dodecane to simultaneously produce low molecular weight hydrocarbons (HCs) and H₂. These reforming products served as reductants and promoters for the selective catalytic reduction (SCR) of NO_x over Ag/Al₂O₃. N₂ adsorption-desorption, X-Ray powder diffraction, H₂ temperature programmed reduction, and thermogravimetric analysis were performed for Ni-based catalysts. It was shown that an increase in the redox performance of Ni-based catalysts enhanced the H₂ production from fuel reforming but decreased the amount of HCs available for further SCR reaction. The temperature window for NO_x removal using the coupled system shifted to lower temperatures at the expense of the NO_x conversion. An optimal ratio of H₂/HCs was achieved using a Ni/ZrO₂+Ag/Al₂O₃ dual catalyst system, which exhibited high activity for NO_x conversion at typical diesel exhaust temperatures. Studies on the durability and performance of this Ni/ZrO₂+Ag/Al₂O₃ coupled system were also performed, and the results showed that the lifetime of the reforming catalyst may limit the system and requires further improvement.

1. Introduction

Diesel engines are currently popular in industry and motor vehicles because of their excellent power performance and cost effectiveness. However, the issue of NO_x removal from diesel engine exhaust remains a major barrier to more widespread usage. The lean-burn characteristics of diesel engines results in low efficiency for NO_x reduction by three-way catalysts [1], as selective catalytic reduction (SCR) of NO_x exhibits highest performance in oxygen-rich conditions. Because of its superior NO_x removal efficiency, an urea/NH₃-SCR system has been commercially used in Europe, the United States, and Japan. However, this complex exhaust treatment facility is expensive and has

potential for secondary pollution caused by NH₃ leakage [2]. To avoid these problems, hydrocarbon (HC)-SCR technology that employs on-board fuel as the source of reductant has drawn considerable interest in recent years.

It has been demonstrated that numerous catalysts such as zeolitic oxide, base metal/oxides, and noble metal catalysts are effective for NO_x removal by HC-SCR in the presence of excess oxygen [2–6]. Among them, alumina-supported silver (Ag/Al₂O₃) is a particularly promising catalyst for practical application [1,7–9]. The NO_x abatement efficiency of HC-SCR not only depends on the nature of the catalysts but also on the structure and composition of the reductants used [8–12]. Generally, the efficiency of reductants for NO_x removal over

Ag/Al₂O₃ drops in the sequence of oxygenated HCs (alcohols, aldehydes, ketones etc.) > linear paraffins > branched paraffins > cycloalkanes. For linear paraffins, the light-off temperature for NO_x reduction decreases with increasing chain length. It has been reported that the light-off temperature for NO_x reduction using a 2% Ag/Al₂O₃ catalyst decreased from 675 K to 525 K as chain length was decreased from C₈ to C₁ [8]. Higher normal alkanes exhibited higher reaction rates for NO_x reduction but decreased values of maximum NO_x conversion [13]. Under HC/NO_x ratio of 6, gas hourly space velocity (GHSV) of 60000 h⁻¹, the activity of 2% Ag/Al₂O₃ for NO_x reduction by C₈H₁₈ was tested by Eränen et al. [14], during which about 90% NO_x conversion was achieved in a temperature range of 720–770 K. With *n*-dodecane as a reductant, Yoon et al. [15] achieved the highest NO_x conversion of ca. 75% over 2% Ag/Al₂O₃ (GHSV = 30000 h⁻¹). When *n*-C₁₆H₃₄ or diesel was applied as a reductant directly, the highest NO_x conversion over 1.9% Ag/Al₂O₃ was only 50% (HC/NO_x = 6, GHSV = 60000 h⁻¹) [16]. Rapid deactivation of Ag/Al₂O₃ because of serious carbon deposition was observed when diesel such as gas-to-liquid (GTL, negligible sulphur and only 0.3 wt% aromatics) and US06 (ultra-low sulphur but 24 wt% aromatics) were used directly as a reductant for NO_x conversion and the catalyst even failed to reach a steady state [10]. In contrast, when using small molecular weight HCs as reductants (e.g., C₃H₆), up to 90% NO_x conversion was achieved using a Ag/Al₂O₃ catalyst over a wide temperature range (700–850 K) [17]. Using ethanol or methanol as reductants, NO_x conversion over 5% Ag/Al₂O₃ catalysts in the range 600–700 K was as high as 100% [18]. Diesel engine bench testing has confirmed that a system of Ag/Al₂O₃-C₂H₅OH showed outstanding NO_x conversion and good durability [19]. A comparison between NO_x reductions over AgAlO₂/Al₂O₃ with diesel fuel and by partial oxidation products of diesel was performed by Nakatsuji et al. [20]. The results showed that partial oxidation products (small molecular weight HCs such as acet-aldehyde) exhibited higher activity for NO_x removal than diesel itself. These results demonstrate that small molecular weight HCs and oxygenated ones are preferable for NO_x reduction over Ag/Al₂O₃ catalysts.

Although H₂ is active for SCR of NO_x over precious metal catalysts at low temperatures [21], for Ag/Al₂O₃ catalysts, H₂ is not an efficient reductant [22–24]. However, the research of Satokawa [25] noted that a small amount of H₂ could significantly improve the activity of Ag/Al₂O₃ for NO_x reduction by C₃H₈ at low temperatures. Since then, considerable attention has been paid to the effect of H₂ on the HC-SCR reaction. During this reaction, it was proposed that the role of H₂ in NO_x reduction is related to the catalyst, reductant, and concentration of added H₂ [26–30]. Zhang et al. [31] reported that the presence of H₂ at 1% significantly enhanced the low temperature activity of 4% Ag/Al₂O₃ for NO_x reduction by C₃H₆ at a GHSV of 50000 h⁻¹ and a HC/NO_x ratio of 6. In this case, 80% NO_x conversion was achieved over a wider range of temperatures (500–800 K) than in the absence of H₂ (650–800 K). To overcome the difficulties and potential dangers of H₂ storage and transportation, in situ H₂ generation by on-board fuel reforming is highly desirable for the application of solid-oxide fuel cells in vehicles

[32–36]. The promotion of NO_x removal by HC-SCR at low temperatures in exhaust aftertreatment systems would also be advantageous [11,37]. During the catalytic reforming process, the metal nickel (Ni) has been extensively utilized as an active component because of its superior C–C bond cleavage ability, low cost, and ready availability [38,39]. The catalytic performance of Ni-based catalysts, such as the distribution of reforming products and durability, has been found to be closely related to the nature of the support [40–42]. Such features provide an opportunity for simultaneous generation of H₂ and small molecular HCs if Ni-based catalysts were to be used in catalytic reforming of on-board fuel.

Inspired by the previous works, catalytic reforming of *n*-dodecane by Ni-based catalysts (representative of on-board fuel) was investigated, producing both H₂ and small molecular HCs. This system was coupled with a 4 wt% Ag/Al₂O₃ catalyst for HC-SCR, and the influence of the different supports employed in Ni-based catalysts on NO_x conversion was examined under a simulated atmosphere.

2. Experimental

2.1. Catalyst preparation

All materials were analytical reagent grade purchased from Sinopharm Chemical Reagent Co., Shanghai, China. Metal oxides (La, Ce, and Zr) were prepared by a homogeneous precipitation method with the corresponding metal nitrate as precursor and urea as the precipitant [43]. The precipitates were dried in an oven at 373 K overnight and were then calcined at 873 K for 5 h in air. Utilizing the above metal oxides and commercial boehmite as supports, 5 wt% Ni-based catalysts were prepared using an impregnation method. Specifically, a certain amount of support (5 g) was added into a Ni(NO₃)₂ solution (50 ml, 0.085 mol/L) and stirred at room temperature for 1 h, and then the excess water was removed by rotary evaporation at 333 K under vacuum condition. The resulting solids were dried at 373 K overnight and then calcined at 873 K for 3 h in air. Before measurement, the samples were crushed and sieved to ensure that particles were between 20 and 40 mesh in size.

As described elsewhere [12], 4 wt% Ag/Al₂O₃ catalyst was prepared by an impregnation method, immersing boehmite into an aqueous solution of AgNO₃.

2.2. Catalyst characterization

Powder X-ray diffraction (XRD) was performed using an X' Pert Pro type diffractometer (PANalytical, Netherlands) with a Cu K_α source (λ = 0.154056 nm). The patterns were measured over a 2θ range of 10°–90° with a scan speed of 4°/min.

The specific surface area and pore characterization of the catalysts were obtained by N₂ adsorption/desorption analysis at 77 K using a Quadrasorb-18 automated gas sorption analyzer (Quantachrome, USA). Prior to N₂ physisorption, the catalysts were degassed at 573 K for 5 h.

Hydrogen temperature-programmed reduction (H₂-TPR) was performed on an AutoChem II 2920 type chemisorption

analyzer (Micromeritics, USA) using 10% H₂/Ar within a temperature range of 323–1273 K and a ramp rate of 10 K/min.

Thermogravimetric analysis (TG) of used samples was carried out on a TGA/DSC 1 (STAR[®] System, Mettler Toledo USA) in an O₂ atmosphere within a temperature range of 300–1000 K at a ramp rate of 20 K/min.

2.3. Activity test

n-dodecane (*n*-C₁₂H₂₆, analytical reagent grade, 99.8%, Tianjin Fuchen Chemical Reagents Factory, China) was chosen to be representative of on-board diesel for catalytic reforming. Activity testing was carried out on a fixed-bed continuous evaluation equipment controlled by a computer. Two tubular furnaces were employed in the evaluation equipment, in which the former one with two heating areas worked for evaporating liquid reactants and reforming reaction, and the latter one worked for SCR reaction. The liquid reactants of *n*-dodecane and water for the reforming reaction were precisely controlled by micro-pumps (HARVARD, PHD 2000 Infusion), with injection rates of 13 and 30 μl/min, respectively. The reagents were volatilized at 573 K, and the gas was fed into the catalyst bed by a stream of N₂ at 1 atm with a flow rate of 205 ml/min. Conditions for reforming were set as follows: H₂O/O₂/C = 2.45/0.5/1 (ca. 2.2% O₂), N₂ balance, W/F = 0.072 (g·s)/ml, reaction temperature 773 K. After being condensed by an equipment with a circular outline (the temperature of which was set at 273 K), the gas phase reforming products were then introduced into the SCR reaction zone, in which the reaction conditions were set as follows: NO_x 0.1%, O₂ 10%, N₂ balance, W/F = 0.018 (g·s)/ml. The concentrations of NO and NO₂ were detected by a Fourier transform infrared spectrometer equipped with a gas cell (Nicolet is10, 0.2 dm³ gas cell, 393 K), and each data point was recorded after stabilization at the preset temperature for 35 min. The concentrations of H₂, CO₂, and total HCs before and after the SCR reaction were measured by a gas chromatograph (GC, Shimadzu, GC-2014C) equipped with two thermal conductivity detectors (TCD) and one flame ionization detector (FID). Gas of O₂, N₂, CO₂, and C₂H₄ flow through Porpack-N column (80–100 mesh, 3.2 mm × 2.1 mm × 1.0 m) and were detected by TCD1; H₂ flow through MS-13X column (80–100 mesh, 3.2 mm × 2.1 mm × 2.0 m) and was detected by TCD2; oxygenated HCs such as CH₃CH₂OH and CH₃COCH₃ were separated by Rtx-Wax capillary column (0.53 mm × 1 μm × 30 m) and detected by FID. The simplified flow path of the coupling system is shown in Fig. 1.

3. Results and discussion

3.1. Structural properties

Figure 2 displays the XRD patterns of Ni-based catalysts supported on different oxides. Supports prepared by homogeneous precipitation were present as La₂O₂CO₃ (JCPDS 84-1963) with hexagonal structure, CeO₂ (JCPDS 43-1002) with cerianite structure, and ZrO₂ as a composite of tetragonal (JCPDS 50-1089) and monoclinic (JCPDS 37-1484) structures, respectively. After 5% Ni was loaded, weak NiO features (JCPDS 04-0850) were detected, indicating a good dispersion of Ni species. The Ni/Al₂O₃ catalyst prepared from boehmite exhibited the characteristic patterns of NiAl₂O₄ (JCPDS 10-0339) and Al₂O₃ (JCPDS 74-2206) simultaneously. The specific surface area and pore structural parameters of the Ni-based reforming catalysts are listed in Table 1. Compared with the 5% Ni/Al₂O₃ catalyst, samples prepared by the homogeneous precipitation method gave lower surface area and smaller pore volume and diameter.

3.2. Catalytic performance

The activity of the Ni-based catalyst + Ag/Al₂O₃ coupled system for NO_x reduction is shown in Fig. 3. For comparison, *n*-dodecane was used directly as a reductant for NO_x removal over Ag/Al₂O₃ (hereafter denoted as *n*-C₁₂H₂₆-SCR), during which NO_x conversion was only 5% at 525 K. The high light-off characteristics of *n*-dodecane for NO_x reduction may be at-

Conditions for the reforming reaction: H₂O/O₂/C = 2.45/0.5/1 (ca. 2.2% O₂), 573 K vaporization, N₂ balance, W/F = 0.072 (g·s)/ml, 773 K. Conditions for SCR reaction: NO_x 0.1%, O₂ 10%, N₂ balance, W/F = 0.018 (g·s)/ml.

tributed to its high boiling point, making it prone to accumulation on the catalyst surface at lower temperatures, resulting in decreased activity [16]. As temperature increased NO_x reduction by *n*-dodecane showed a sharp increase at 650 K and maintained around 78% conversion over a wide temperature range of 673–823 K. Having achieved catalytic reforming of *n*-C₁₂H₂₆ over the Ni-based catalysts on different supports, downstream conversion of NO_x over Ag/Al₂O₃ was investigated. After catalytic reforming of *n*-C₁₂H₂₆ over Ni/Al₂O₃, NO_x conversion over Ag/Al₂O₃ increased to 90% within a temperature range of 673–800 K. The optimal temperature range of the Ni/ZrO₂ and Ag/Al₂O₃ coupled system for NO_x conversion was 100 K lower than that of the *n*-C₁₂H₂₆-SCR system, giving a highest NO_x conversion of 90% at 750 K. This dual catalyst system therefore showed improved NO_x purification efficiency in the typical diesel exhaust temperature range of 573–773 K (NO_x conversion > 60%). Compared to a Ni/ZrO₂+Ag/Al₂O₃ coupled system, the combination of Ni/CeO₂ with Ag/Al₂O₃ was found to further improve the low-temperature activity for NO_x reduction, with the active temperature range of the catalyst 100 K lower than the Ni/ZrO₂+Ag/Al₂O₃ coupled system. NO_x conversion decreased sharply at temperatures above 600 K (reaching a maximum of 80% at 550 K and then decreasing as temperature was increased further). When Ag/Al₂O₃ was coupled with Ni/La₂O₂CO₃, NO_x conversion at 375–475 K was 10% higher than for the Ni/CeO₂+Ag/Al₂O₃ coupled system, but the highest NO_x conversion observed was lower (60% at 500 K). Using this dual catalyst system, the decrease in NO_x conversion at temperatures above 500 K was also pronounced.

The mechanism of the H₂ effect in HC-SCR over Ag/Al₂O₃ is still under intense debate, but it has been generally accepted that the presence of H₂ promotes partial oxidation of HCs and affects NO_x reduction, particularly at low temperatures [24,31,44,45]. The influence of H₂ on the activity of Ag/Al₂O₃ catalysts for NO_x reduction has been found to be strongly dependent on the reaction conditions, for example, the concentra-

tions of reductant and H₂, ratio of HC/NO_x, reaction temperature, space velocity, and so on. Lee et al. [11] investigated the activity of 2% Ag/Al₂O₃ for C₃H₆/C₈H₁₈-SCR, during which NO_x conversion significantly improved from 0% to 64% at 523 K with an increase of the H₂/N ratio from 0 to 10. The H₂ promotion effect was also evaluated on a diesel engine by using a Ag/Al₂O₃-coated monolith catalyst by Sitshebo et al. [37]. At low engine loads (HC/NO_x ≈ 0.9, 17% O₂, 375 K), NO_x conversion gradually improved with increasing H₂ concentration (H₂/N = 0–14). At higher engine loads (HC/NO_x ≈ 0.5, O₂ 10.7%, 535 K), complete oxidation of HC occurred only when the H₂/N ratio was above 2.25, leading to reduced NO_x conversion. Recently, SCR of C₃H₆ and C₁₂H₂₆ assisted by catalytic partial oxidation reforming of *n*-C₁₂H₂₆ over a diesel fuel cracking catalyst was performed by Lee et al. [11], in which an optimum ratio (H₂/HC) was required for NO_x reduction at low temperatures over Ag/Al₂O₃.

Based on this literature, we also investigated the effect of H₂ concentration on HC/NO_x and NO_x conversion over different coupled systems at 650 K (Table 2). At the beginning of the reforming reaction over Ni/Al₂O₃, about 10.3% of the reductant was completely oxidized to CO₂, producing 0.03% H₂ and HCs with a HC/NO_x ratio of 10 available for further SCR reaction. Over the coupled Ag/Al₂O₃ catalyst system, 57% NO_x conversion was observed. As for fuel reforming over Ni/La₂O₂CO₃, initial H₂ production increased to 2.74%, giving the lowest HC/NO_x ratio of 5 for SCR reaction and the lowest NO_x conversion of 30% among the all tested dual catalyst systems. After running for 3 h, the H₂ concentration decreased to 0.98% over Ni/La₂O₂CO₃, indicating a poor durability for fuel reforming. The second-highest H₂ concentration (2.15%) was obtained during the catalytic reforming of *n*-C₁₂H₂₆ over Ni/CeO₂, leaving the second-lowest HC concentration for NO_x reduction and thus the second-lowest NO_x conversion (52%). Among the tested systems, the Ni/ZrO₂+Ag/Al₂O₃ coupled system achieved the highest NO_x conversion (around 88%) at a temperature of 650 K, with a H₂ concentration of 1.12% and a HC/NO_x ratio of 7.5. The combined results presented in Table 2 and Fig. 2 show that the support employed in the Ni-based catalysts had a remarkable influence on the catalytic reforming performance. As H₂ concentration from fuel reforming increased, the coupled SCR catalyst for NO_x reduction gave a higher activity at low temperatures. Conversely, as H₂ yield increased and complete oxidation of HC was promoted, HCs became unavailable for subsequent SCR reactions. This feature may have contributed to the decrease in the maximum NO_x conversion achieved on our dual

Fig. 4. H_2 -TPR profiles of the Ni-based catalysts supported on different oxides. (1) 5% Ni/La₂O₂CO₃; (2) 5% Ni/CeO₂; (3) 5% Ni/ZrO₂; (4) 5% Ni/Al₂O₃.

catalyst systems. After catalytic reforming, a higher H_2 yield was commonly accompanied by a lower concentration of HCs, possibly suggesting that complete oxidation of HCs was promoted by excess H_2 . It is also noteworthy that the HCs in the reforming products were mainly small molecular weight oxygenated HCs with less than 4 carbon atoms according to GC analysis. The small molecular weight oxygenated HCs were likely beneficial for NO_x reduction.

3.3. Redox performance of reforming catalysts

Generally, H_2 production from catalytic reforming of HC was closely related to the redox performance of the employed catalyst and interactions between the active component and support [46–48]. To highlight this issue, H_2 -TPR measurements were carried out on the Ni-based catalysts, with results shown in Fig. 4 and Table 3. Over Ni/Al₂O₃, a strong interaction between Ni species and the support resulted in the formation of the NiAl₂O₄ spinel structure, reduction of which occurred at temperatures above 800 K, exhibiting a wide H_2 consumption peak within the range 800–1120 K. During H_2 reduction of Ni/ZrO₂, two peaks emerged, centered at 598 and 703 K. The low-temperature peak could be assigned to the reduction of surface-dispersed NiO particles and the high-temperature peak to reduction of a NiO species weakly interacting with ZrO₂ [49]. The H_2 consumption of the above two peaks was 758 $\mu\text{mol/g}$, slightly lower than that required for complete reduction of NiO

(845 $\mu\text{mol/g}$, hereafter denoted as the theoretical value), indicating a good dispersion of Ni species, which was confirmed by the XRD analysis. Similarly, two peaks centered at 608 and 700 K were observed on Ni/CeO₂. The first feature began at 450 K and was assignable to the reduction of surface adsorbed oxygen on the surface of CeO₂ and dispersed NiO species. The high temperature peak was attributed to the reduction of bulk-like NiO and the CeO₂ interacting with Ni species [50]. A reduction of bulk CeO₂ was also observed for this catalyst at 983 K. Over Ni/La₂O₂CO₃, a strong H_2 consumption peak centered at 975 K was induced by reduction of bulk La³⁺ [51]. The reduction of the NiO surface also resulted in a sharp peak at 590 K, the H_2 consumption of which was 792 $\mu\text{mol/g}$ and approached theoretical maximum reduction (94%). Considering that there was only one peak centered at 975 K in the H_2 -TPR profile of La₂O₂CO₃, the peak at 758 K observed over Ni/La₂O₂CO₃ may have resulted from reduction of the active components having intimate interaction with the support.

By carefully comparing the H_2 -TPR results of Ni-based catalysts supported on different oxides, Sato et al. [52] identified that superior redox performance of Ni/Ce_{0.5}Zr_{0.5}O₂ was crucial for ethanol reforming at low temperatures. On a molecular level, De Lima et al. [53] revealed the key role of surface oxygen species in guaranteeing the stability of Pt/CeZrO₂ catalyst for oxidative steam reforming of ethanol. As shown in Fig. 4, the reduction temperature peaks of surface-dispersed NiO (peak 1) over catalysts prepared by the homogeneous precipitation method were centered at similar temperatures (around 600 K), but the reduction onset temperature for Ni/CeO₂ and Ni/La₂O₂CO₃ was much lower than that of Ni/ZrO₂ (450 K for the former two and 540 K for the latter), indicating that the former two were more readily reduced at low temperatures. The ratios of the H_2 consumption to the theoretical value for peak 1 are listed in Table 3, where ratios of 27%, 64%, and 94% were determined for Ni/ZrO₂, Ni/CeO₂, and Ni/La₂O₂CO₃, respectively. The larger amount of reducible surface NiO species gave a higher reducibility at low temperatures. As the reducibility of Ni-based catalysts increased at low temperatures, H_2 production from fuel reforming was enhanced, and the amount of HCs available for further SCR reactions was reduced (Table 2). Therefore, the temperature range for NO_x removal over the coupled system shifted to lower temperatures at the expense of maximum NO_x conversion efficiency. The results presented above clearly show the critical role of the redox performance of the reforming catalyst in NO_x reduction over the coupled system of reforming-SCR catalysts. With Ni/ZrO₂, having a moderate reducibility, optimal concentrations of H_2 and HCs were determined for the Ni/ZrO₂+Ag/Al₂O₃ coupled system reforming process giving outstanding NO_x reduction efficiency at typical diesel exhaust temperatures.

3.4. Catalytic durability

As can be seen from Table 2, H_2 generation from the reforming reaction over Ni-based catalysts decreased by different degrees over time, which was likely related to deposition of carbon on the surface of the catalysts [53]. Therefore, TG anal-

Fig. 5. TG analysis of Ni-based catalysts supported on different oxides after 3 h operating for n -C₁₂H₂₆ reforming. (1) 5% Ni/La₂O₂CO₃; (2) 5% Ni/CeO₂; (3) 5% Ni/ZrO₂; (4) 5% Ni/Al₂O₃.

ysis was conducted on reforming catalysts that had been used for 3 h at 873 K, with results shown in Fig. 5. A weight loss of 21.57% was observed from the used Ni/Al₂O₃, indicating considerable carbon deposition. An average rate of carbon deposition of 0.072 g-C/(g-cat·h) over Ni/Al₂O₃ was calculated based on the loss rate per unit time and per unit weight of catalyst. It should be noted that C₂H₄ with a relative concentration of about 0.15% was detected by GC during the reforming of n -C₁₂H₂₆ over Ni/Al₂O₃, while this compound was not detected from other reforming catalysts. This result further suggested that the strong surface acidity of Al₂O₃ contributed to the formation of C₂H₄, as a major byproduct during H₂ production from the reforming process. The occurrence of C₂H₄ is likely linked to the high rate of carbon deposition [46]. The weight loss of Ni-based catalysts supported on ZrO₂, CeO₂, and La₂O₂CO₃ was considerably less than Ni/Al₂O₃, at 9.58%, 8.24%, and 6.17%, respectively. Clearly, the redox performance of the reforming catalyst not only affected the yield of H₂ but also contributed to its durability in the reforming process. Higher redox performance for the reforming catalyst inhibited carbon deposition and guaranteed longer lifetimes, which is in accordance with previous reports [47,48]. In addition, the reaction of La₂O₂CO₃ + C → La₂O₃ + 2CO occurred during reforming of n -C₁₂H₂₆ over Ni/La₂O₂CO₃, which may further reduce carbon deposition [51].

With consideration of the excellent NO_x removal efficiency of the Ni/ZrO₂+Ag/Al₂O₃ system, time dependence of H₂ production at 773 K and NO_x conversion at 650 K were measured using this system (Fig. 6). During the first 2 h, there was a slight drop in H₂ concentration, which may have contributed to a decrease in NO_x conversion. In the following 3 h, H₂ concentration remained at a level of about 1%, and NO_x conversion remained relatively stable (around 88%). As reaction continued, the H₂ concentration showed a sharp drop to around 0.2% after 10 h, followed by a slow decrease over the next 14 h. The lower H₂ concentration led to a corresponding decline in NO_x conversion although the rate of decline of NO_x conversion was much slower than decrease in that of H₂ concentration. As a result, NO_x conversion was maintained at 70% even after running for

Fig. 6. Time dependence of NO_x conversion and H₂ concentration (measured before SCR reaction) during the n -C₁₂H₂₆ reforming-SCR over the Ni/ZrO₂+Ag/Al₂O₃ coupled system. Conditions for reforming reaction: H₂O/O₂/C = 2.45/0.5/1 (ca. 2.2% O₂), 573 K vaporization, N₂ balance, W/F = 0.072 (g·s)/ml, 773 K. Conditions for SCR reaction: NO 0.1%, O₂ 10%, N₂ balance, W/F = 0.018 (g·s)/ml, 650 K.

24 h. During TG analysis of the Ni/ZrO₂ sample from 24 h of operation, a weight loss of 16.5% was observed within the temperature range of 573–873 K. This provided evidence of carbon deposition and suggested an area for further improvement.

4. Conclusions

The redox performance of Ni-based catalysts strongly depends on the nature of the support used in the catalyst preparation. The choice of support may affect the concentrations of H₂ and HCs with small molecular weight that form during the catalytic reforming of n -C₁₂H₂₆. This in turn affects the NO_x conversion over the fuel reforming-SCR coupled system. An optimal concentration ratio of H₂ to low HCs could be found for some systems (e.g., H₂ 1.1%, HC/NO_x = 7.5 during fuel reforming over Ni/ZrO₂). A coupled system of Ni/ZrO₂+Ag/Al₂O₃ demonstrated high efficiency for NO_x conversion at typical diesel exhaust temperatures. Carbon deposition over Ni-based catalysts induced a decrease in H₂ production and thus lowered NO_x conversion from the fuel reforming-SCR coupling system.

Fuel reforming over Ni-based catalysts coupled with selective catalytic reduction of NO_x

ZHAO Jiaojiao, YU Yunbo*, HAN Xue, HE Hong

Research Center for Eco-Environmental Sciences, Chinese Academy of Sciences

Small molecular weight hydrocarbons and H₂ produced from on-board fuel reforming over Ni-based catalysts were used as reductants in the selective catalytic reduction of NO_x over Ag/Al₂O₃ catalysts at typical diesel exhaust temperatures.

Ni基催化剂催化燃油重整耦合选择性催化还原NO_x反应

赵娇娇, 余运波*, 韩雪, 贺泓

中国科学院生态环境研究中心, 北京100085

摘要: 分别以 $\text{La}_2\text{O}_3\text{CO}_3$, CeO_2 , ZrO_2 和 Al_2O_3 为载体, 采用浸渍法制备了Ni基重整催化剂, 并以正十二烷模拟车载燃油进行催化重整反应以同时制备小分子碳氢化合物(HCs)和 H_2 , 考察了其在4 wt% $\text{Ag}/\text{Al}_2\text{O}_3$ 上选择性催化还原(HC-SCR)氮氧化物(NO_x)的性能. 采用 N_2 吸附-脱附、X射线粉末衍射、 H_2 程序升温还原和热重等手段对Ni基催化剂进行了表征. 结果表明, 随着重整催化剂氧化还原性能增强, 产物中 H_2 浓度增加, 可参与SCR反应的HCs含量减少, 从而导致重整-SCR耦合体系上 NO_x 净化活性温度窗口向低温移动, NO_x 最高转化率降低. Ni/ $\text{ZrO}_2+\text{Ag}/\text{Al}_2\text{O}_3$ 耦合体系中 H_2/HCs 符合SCR反应所需的最优比例, 在柴油车典型排气温度范围内表现出良好的 NO_x 净化能力. 同时, 在Ni/ $\text{ZrO}_2+\text{Ag}/\text{Al}_2\text{O}_3$ 耦合体系上考察了其燃油重整-SCR的活性稳定性. 结果显示, 重整催化剂的耐久性有待进一步提高.

1. 前言

柴油机以其优良的动力性与经济性成为未来机动车发展的主流方向之一, 然而尾气中氮氧化物(NO_x)的净化是其进一步推广应用的一大瓶颈. 柴油机的稀燃特性导致三效催化剂不能有效发挥作用^[1], 在这种 O_2 过量的条件下, 选择性还原技术(SCR)表现出较高的 NO_x 净化效率. 在欧洲、美国、日本等国以尿素为还原剂的Urea/ NH_3 -SCR技术已商业化应用于柴油车尾气 NO_x 排放控制, 但该技术仍存在尾气后处理系统复杂、尿素添加站建设投资大、氨泄漏引发二次污染等缺陷^[2]. 以车载燃油为还原剂来源的碳氢化合物选择性催化还原 NO_x 技术(HC-SCR)则可以有效地避免以上问题, 引起了研究者的广泛关注.

研究表明^[2~6], 分子筛、碱金属/氧化物和贵金属等催化剂具备催化HC选择性还原 NO_x 的能力. 其中, 银/氧化铝($\text{Ag}/\text{Al}_2\text{O}_3$)催化剂表现出优异的 NO_x 净化活性及应用前景^[1,7~9]. HC-SCR技术净化 NO_x 的效率不仅与催化剂的性能密切相关, 同时与所选用还原剂的结构及用量相关^[8~12]. 一般来说, $\text{Ag}/\text{Al}_2\text{O}_3$ 催化不同结构还原剂选择性催化还原 NO_x 的活性顺序为: 含氧烃类(醇、醛、酮等)>直链烃类>支链烃类>环状烃类. 对直链烷烃还原剂而言, SCR反应起燃温度随链长的增加而降低: 链长由 C_1 增加至 C_8 时, 2% $\text{Ag}/\text{Al}_2\text{O}_3$ 催化净化 NO_x 的起燃温度由675 K降至525 K^[8]. NO_x 还原反应速率随直链烷烃碳链增长而增加^[13], 但 NO_x 最高去除效率降低. Eränen等^[14]在 $\text{HC}/\text{NO}_x = 6$, $\text{GHSV} = 60000 \text{ h}^{-1}$ 条件下考察了2% $\text{Ag}/\text{Al}_2\text{O}_3$ 上 C_8H_{18} -SCR的反应活性, 在720~770 K NO_x 最高转化率可达90%. Yoon等^[15]考察了2% $\text{Ag}/\text{Al}_2\text{O}_3$ 催化正十二烷选择性还原 NO_x 的活性, 发现 NO_x 最高转化率约为75% ($\text{GHSV} = 30000 \text{ h}^{-1}$). 而直接以 $n\text{-C}_{16}\text{H}_{34}$ 或柴油作

为还原剂时, 在1.9% $\text{Ag}/\text{Al}_2\text{O}_3$ 上 NO_x 的最高转化率仅为50% ($\text{HC}/\text{NO}_x = 6$, $\text{GHSV} = 60000 \text{ h}^{-1}$)^[16]. 以柴油如GTL (Gas-to-Liquid, 含0.3 wt% 芳香烃, S含量可忽略)或US06 (超低S含量, 24 wt% 芳香烃)等作为还原剂时, $\text{Ag}/\text{Al}_2\text{O}_3$ 催化剂容易积碳并在很短时间内迅速失活(甚至未能达到稳态)^[10]. 与此相反, 以 C_3H_6 等小分子碳氢化合物为还原剂时, 在较宽的温度区间内 (700~850 K), 4% $\text{Ag}/\text{Al}_2\text{O}_3$ 催化剂上 NO_x 转化率达90%以上^[17]. 以 $\text{C}_2\text{H}_5\text{OH}$ 或 CH_3CHO 等为还原剂时, 5% $\text{Ag}/\text{Al}_2\text{O}_3$ 上 NO_x 转化率在600~700 K范围内高达100%^[18]; 发动台架试验进一步表明, $\text{Ag}/\text{Al}_2\text{O}_3\text{-C}_2\text{H}_5\text{OH}$ 的组合体系具备了较优异的 NO_x 净化效率与耐久性^[19]. Nakatsuji等^[20]以柴油作为还原剂来源, 对比了柴油直接为还原剂或经部分氧化后对 $\text{AgAlO}_2/\text{Al}_2\text{O}_3$ 催化 NO_x 净化性能的影响, 结果显示, 柴油部分氧化产物(乙醛等含氧小分子)在HC-SCR反应中具有更高的反应活性. 综上所述, 小分子HCs及含氧HCs是 $\text{Ag}/\text{Al}_2\text{O}_3$ 净化 NO_x 的优选还原剂.

H_2 在贵金属催化的SCR反应中表现出优异的低温活性^[21]. 但是, 以 $\text{Ag}/\text{Al}_2\text{O}_3$ 为催化剂时 H_2 并不是有效的还原剂^[22~24]. Satokawa^[25]发现, 少量 H_2 的存在能显著提高 $\text{Ag}/\text{Al}_2\text{O}_3$ 催化 C_3H_8 选择性还原 NO_x 的低温活性. 随后, HC-SCR反应中的 H_2 效应广受关注. 研究表明^[26~30], HC-SCR反应中 H_2 的作用与催化剂类型、还原剂种类及 H_2 添加量密切相关. Zhang等^[31]的研究显示, 在 $\text{GHSV} = 50000 \text{ h}^{-1}$, $\text{C}/\text{N} = 6$ 条件下, 1% H_2 的添加有效促进了4% $\text{Ag}/\text{Al}_2\text{O}_3$ 上 C_3H_6 -SCR反应的低温活性, 将 NO_x 还原温度窗口向低温拓宽了150 K, 并在500~800 K实现 NO_x 转化80%以上. 为应对 H_2 储存和运输过程中存在的困难和潜在问题, 众多国内外学者致力于燃油催化重整或等离子体重整原位制备 H_2 的研究^[32~36], 为车载电池供给燃料或为基于HC-SCR反应的 NO_x 净化后处理提供助剂^[11,37].

在催化重整反应中, Ni因其强催化C–C键断裂能力和便宜易得而备受关注^[38,39]。同时, Ni基催化剂的重整性能如重整产物分布、催化剂耐久性等与载体性质密切相关^[40–42], 这为本文重整柴油组分同时制备H₂及高活性HCs小分子提供了可能。

基于以上研究, 本文选用正十二烷作为车载柴油模拟组分, 以镍基催化剂催化正十二烷重整同时制备小分子HCs和H₂, 并与高效HC-SCR催化剂4 wt% Ag/Al₂O₃耦合, 在实验室模拟气氛条件下考察了不同氧化物负载的重整催化剂对耦合体系净化NO_x性能的影响。

2. 实验部分

2.1. 催化剂的制备

分别以La, Ce和Zr的硝酸盐为前驱体, 尿素为沉淀剂, 采用均匀沉淀法^[43]制备La, Ce和Zr的氧化物, 373 K烘箱中过夜干燥, 空气气氛中873 K焙烧5 h后作为载体备用。以上述氧化物及市售拟薄水铝石为载体(或载体前驱体), 采用浸渍法制备5 wt%的Ni基重整催化剂, 具体步骤如下: 将所需量的载体(如5 g)加入Ni(NO₃)₂溶液(50 ml, 0.085 mol/L)中, 室温搅拌1 h, 于333 K下真空旋蒸, 373 K过夜干燥, 空气气氛中873 K焙烧3 h, 粉碎, 过筛备用(20~40目)。

参照文献[12]方法制备4 wt% Ag/Al₂O₃催化剂。以上实验药品均购自国药集团试剂有限公司, 分析纯。

2.2. 催化剂的表征

X射线粉末衍射(XRD)表征在荷兰PANalytical公司的X'Pert Pro型X射线衍射仪上进行, Cu K_α射线($\lambda = 0.154056$ nm), 扫描范围 $2\theta = 10^\circ \sim 90^\circ$, 扫描速度 $4^\circ/\text{min}$ 。样品的比表面积、平均孔径和总孔体积采用美国康塔公司的Quantasorb-18全自动比表面分析仪测定。测试之前, 样品在573 K脱气处理4 h, 然后在77 K下进行N₂吸附-脱附等温线的测定。程序升温还原(H₂-TPR)表征在美国麦克仪器公司的AutoChem II 2920型吸附仪上进行, 催化剂装量100 mg, 反应气氛为10% H₂-90% Ar, 测试温度为323~1273 K, 升温速率10 K/min。反应后样品的热重(TG)分析在Mettler Toledo公司的TGA/DSC 1(STAR[®] System)上进行, 反应气氛为O₂ (50 ml/min), 测试温度为300~1000 K, 升温速率20 K/min。

2.3. 催化剂的评价

以正十二烷(*n*-C₁₂H₂₆, 分析纯, 99.8%, 天津福晨化学试剂有限公司)模拟车载燃油进行重整反应。催化剂活性评价在计算机控制的固定床连续评价装置上进行。

反应装置包括两个管式反应炉, 其一为两段式加热炉用于液态反应物的蒸发和重整反应, 另一用于SCR反应。重整反应区液态反应物*n*-C₁₂H₂₆和H₂O用微型注射泵(HARVARD, PHD 2000 Infusion)精确控制添加, 注入速率分别为13 $\mu\text{l}/\text{min}$ 和30 $\mu\text{l}/\text{min}$, 经573 K管式炉汽化后以N₂为载气吹扫进入重整反应炉。重整反应条件为: H₂O/O₂/C = 2.45/0.5/1 (约2.2% O₂), N₂平衡气, W/F = 0.072 (g·s)/ml, 反应温度773 K。重整产物经过273 K循环冷凝设备后通入SCR反应炉。SCR反应条件为: 0.1% NO_x, 10% O₂, N₂平衡气, W/F = 0.018 (g·s)/ml, 总气体流量1000 ml/min。NO与NO₂的浓度采用配备气体池的傅里叶变换红外光谱仪(Nicolet is10, 0.2 dm³气体池, 393 K)检测, 每个测试点达预设温度35 min后采集数据; SCR反应前后H₂, CO₂及HC总浓度采用气相色谱仪(Shimadzu公司, GC-2014C型, 配备2个TCD检测器, 1个FID检测器)检测。O₂, N₂, CO₂和C₂H₄经Porpack-N柱(80~100目, 3.2 mm × 2.1 mm × 1.0 m)分离, 由TCD1检测; H₂经MS-13X分子筛柱(80~100目, 3.2 mm × 2.1 mm × 2.0 m)分离并由TCD2检测; 含氧HC如CH₃CH₂OH和CH₃COCH₃等经Rtx-Wax毛细管柱(0.53 mm × 1 μm × 30 m)分离后由FID检测。耦合反应的简易流程如图1所示。

3. 结果与讨论

3.1. 重整催化剂结构性质

图2为不同载体负载的重整催化剂样品的XRD谱图。由此可见, 以拟薄水铝石为前驱体负载Ni后焙烧获得的样品为NiAl₂O₄ (JCPDS 10-0339)与Al₂O₃ (JCPDS 74-2206)的复合相; 均匀沉淀法制备的载体分别为六方结构的La₂O₂CO₃ (JCPDS 84-1963)、方钨矿结构的CeO₂ (JCPDS 43-1002), 以及四方结构(JCPDS 50-1089)和单斜晶型(JCPDS 37-1484)复合的ZrO₂。采用浸渍法在上述载体上负载5 wt%的Ni后, 仅在ZrO₂上出现微小的NiO (JCPDS 04-0850)衍射峰, 表明Ni物种在各载体分散良好。不同载体负载的Ni催化剂的比表面积和孔结构信息列于表1。与5% Ni/Al₂O₃催化剂相比, 采用均匀沉淀法制备的载体负载Ni后, 比表面积、平均孔径和孔体积均较小。

3.2. 催化剂的活性

各Ni基催化剂与Ag/Al₂O₃耦合体系净化NO_x的活性结果见图3。作为对比, 考察了Ag/Al₂O₃催化剂上直接以*n*-C₁₂H₂₆为还原剂(记为*n*-C₁₂H₂₆-SCR)时NO_x的净化效率。在该体系上, 525 K时NO_x转化率仅为5%, 未表现出

低温起燃特性,这可能由于 $n\text{-C}_{12}\text{H}_{26}$ 沸点较高,较低温度时易在催化剂表面累积导致活性降低^[16].随着温度升高,650 K时 NO_x 转化率迅速增大并在673~823 K稳定在78%. $n\text{-C}_{12}\text{H}_{26}$ 经不同载体负载的Ni基催化剂重整后,其在 $\text{Ag}/\text{Al}_2\text{O}_3$ 上还原 NO_x 的效率发生显著变化.经 $\text{Ni}/\text{Al}_2\text{O}_3$ 重整后,673~800 K时 $\text{Ag}/\text{Al}_2\text{O}_3$ 净化 NO_x 的效率较 $n\text{-C}_{12}\text{H}_{26}$ -SCR反应有所提高(至90%). $\text{Ni}/\text{ZrO}_2 + \text{Ag}/\text{Al}_2\text{O}_3$ 耦合体系的活性温度窗口较 $\text{Ag}/\text{Al}_2\text{O}_3$ 单独作用时向低温移动了100 K,最高转化率达90%.可以看出,该体系在573~773 K的典型柴油车尾气温度范围内 NO_x 转化率高于60%,具有相对理想的 NO_x 净化效果.与 $\text{Ni}/\text{ZrO}_2 + \text{Ag}/\text{Al}_2\text{O}_3$ 体系相比, Ni/CeO_2 与 $\text{Ag}/\text{Al}_2\text{O}_3$ 的组合进一步促进了 NO_x 的低温还原,其活性温度窗口继续向低温移动了约100 K,但660 K以上的活性却显著降低(550 K时 NO_x 转化率达最大值80%,后随温度升高而下降). $\text{Ni}/\text{La}_2\text{O}_2\text{CO}_3$ 与 $\text{Ag}/\text{Al}_2\text{O}_3$ 耦合作用时,虽然在375~475 K范围内 NO_x 转化率较 $\text{Ni}/\text{CeO}_2 + \text{Ag}/\text{Al}_2\text{O}_3$ 体系提高约10%,但 NO_x 最高转化率降至60%,在高于500 K时 NO_x 转化率也明显降低.

虽然 H_2 对 $\text{Ag}/\text{Al}_2\text{O}_3$ 催化碳氢化合物选择性还原 NO_x 的作用机理仍饱受争议,但其在低温条件下促进HCs部分氧化并影响 NO_x 转化率的事实已被研究者广泛认可^[24,31,44,45]. H_2 对 $\text{Ag}/\text{Al}_2\text{O}_3$ 上HC-SCR反应活性的影响与反应条件密切相关,如还原剂HCs和 H_2 浓度、 HC/NO_x 比例、反应温度及反应空速等. Lee等^[11]考察了 H_2 添加对2% $\text{Ag}/\text{Al}_2\text{O}_3$ 催化剂上 $\text{C}_3\text{H}_6/\text{C}_8\text{H}_{18}$ -SCR ($\text{HC}/\text{NO}_x = 6$)反应的影响,发现523 K时 NO_x 转化率随 H_2 浓度的增加而显著提高至64% (H_2/N 由0变为10时, NO_x 转化率由0%升至64%). Sitshebo等^[37]在发动机台架上考察了 H_2 对蜂窝载体负载的 $\text{Ag}/\text{Al}_2\text{O}_3$ 催化剂净化 NO_x 效率的影响.结果显示,低负荷条件($\text{HC}/\text{NO}_x \approx 0.9$, 17% O_2 , 375 K)下 NO_x 净化效率随 H_2 浓度的增加($\text{H}_2/\text{N} = 0\sim 14$)而逐渐升高.但在高负荷条件($\text{HC}/\text{NO}_x \approx 0.5$, O_2 10.7%, 535 K)下, H_2/N 超过2.25时会因过量 H_2 促进碳氢化合物的完全氧化而导致 NO_x 的转化率下降. Lee等^[11]进一步研究了柴油裂解催化剂催化 $n\text{-C}_{12}\text{H}_{26}$ 部分氧化重整辅助 C_3H_6 和 $\text{C}_{12}\text{H}_{26}$ 选择性催化还原 NO_x 的反应,结果表明, H_2/HCs 的优化决定了 $\text{Ag}/\text{Al}_2\text{O}_3$ 还原 NO_x 的低温性能.

为此,本文检测了650 K时不同组合体系中 H_2 浓度、HC含量及 NO_x 转化率,结果如表2所示.在 $\text{Ni}/\text{Al}_2\text{O}_3$ 催化重整 $n\text{-C}_{12}\text{H}_{26}$ 时,在反应的初始阶段约有10.3%的HC被完全氧化为 CO_2 , H_2 浓度为0.03%,产物中含有大量碳氢

物种,为随后耦合的 $\text{Ag}/\text{Al}_2\text{O}_3$ 催化剂上SCR反应的发生提供还原剂(HC/NO_x 高达10), NO_x 转化率为57%.经 $\text{Ni}/\text{La}_2\text{O}_2\text{CO}_3$ 催化重整后,产物中初始 H_2 浓度高达2.74%,而HC含量在所有测试的耦合体系中最低($\text{HC}/\text{NO}_x = 5$),从而导致 NO_x 转化率也最低(仅为30%).反应3 h后,重整产物中 H_2 浓度急剧降低至0.98%,表明 $\text{Ni}/\text{La}_2\text{O}_2\text{CO}_3$ 催化重整的稳定性差.经 Ni/CeO_2 重整 $n\text{-C}_{12}\text{H}_{26}$ 的产物中 H_2 浓度(2.05%)仅次于 $\text{Ni}/\text{La}_2\text{O}_2\text{CO}_3$,为后续的SCR反应提供的HC浓度较低(仅比经 $\text{Ni}/\text{Al}_2\text{O}_3$ 重整后高),使得 NO_x 转化率也较低(约为52%),仅高于 $\text{Ni}/\text{Al}_2\text{O}_3 + \text{Ag}/\text{Al}_2\text{O}_3$ 组合体系.其中, $\text{Ni}/\text{ZrO}_2 + \text{Ag}/\text{Al}_2\text{O}_3$ 耦合体系中 H_2 浓度为1.12%, $\text{HC}/\text{NO}_x = 7.5$,该 H_2 和还原剂浓度可能处于较优的 H_2/HC 比例范围内,使得该体系获得了最佳 NO_x 净化效率(650 K时 NO_x 转化率达88%).综合图3和表2可见,重整催化剂的载体显著影响其重整性能.随重整产物中 H_2 浓度增加,耦合SCR反应后 NO_x 低温净化活性升高.但 H_2 产量增加的同时,也促进了HC物种的完全氧化,从而导致SCR反应中还原剂量减少.重整反应产物中 H_2 浓度的增加往往伴随着HC含量的降低,这可能表明过量的 H_2 促进了HCs的完全氧化.此外需要指出,GC检测的结果表明,重整产物多为C原子数小于4的含氧碳氢化合物,该类物种具备优异的 NO_x 还原性能.

3.3. 重整催化剂氧化还原性能

研究表明,HC重整制氢反应体系中 H_2 的产率与催化剂的氧化还原性能及活性组分与载体间的作用密切相关.鉴于此,本文对不同载体负载的Ni基重整催化剂进行了 H_2 -TPR测试,结果见图4和表3.可以看出,在 $\text{Ni}/\text{Al}_2\text{O}_3$ 催化剂上, Ni组分与载体间较强的相互作用导致了 NiAl_2O_4 的形成,该物种在800 K以上才开始被还原,并在800~1120 K范围内出现较宽的 H_2 消耗峰. Ni/ZrO_2 催化剂在550~800 K范围内出现重叠的双还原峰,其峰值分别位于598和703 K;前者归属于表面分散的NiO物种的还原,后者归属于与 ZrO_2 表面具有弱相互作用的NiO物种的还原^[49];以上两峰对应的 H_2 消耗总量为758 $\mu\text{mol/g}$,略低于NiO物种完全还原所需 H_2 量(845 $\mu\text{mol/g}$,随后以理论值表示),表明该催化剂上Ni物种处于高度分散状态,与XRD结果一致.在相近的温度下, Ni/CeO_2 样品的还原也导致了双峰的形成,其峰值分别位于608和700 K;开始于450 K的低温还原峰是由表面吸附氧、表面 CeO_2 及均匀分散的NiO的还原造成的,温度较高的还原峰则对应于与载体相互作用的类体相NiO

与CeO₂的还原^[50]。另外, 983 K处还原峰可归属为Ni/CeO₂样品上部分体相CeO₂的还原。Ni/La₂O₂CO₃样品上位于975 K处的强峰源于体相中La³⁺的还原^[51], 590 K处的尖峰归属为表面NiO的还原, 其H₂消耗量约为792 μmol/g (达理论值的94%)。基于载体La₂O₂CO₃样品仅在975 K附近出现还原峰, 可推测Ni/La₂O₂CO₃催化剂上758 K处的峰可能是与活性组分紧密接触的部分载体还原所致。

通过对比不同氧化物负载的Ni催化剂的H₂-TPR结果, Sato等^[52]发现, Ni/Ce_{0.5}Zr_{0.5}O₂优异的氧化还原性能决定了其重整乙醇的低温性能。De Lima等^[53]在分子水平上证实了Pt/CeZrO₂催化剂上表面氧物种在维持乙醇氧化蒸汽重整反应稳定运行中的关键作用。如图4所示, 均匀沉淀法制备的载体负载活性组分后, 虽然表面分散的NiO还原峰(Peak 1)均位于600 K左右, 但Ni/CeO₂和Ni/La₂O₂CO₃催化剂上该还原峰起始于450 K, 较Ni/ZrO₂样品的低(起始于540 K), 表明前两种催化剂的低温氧化还原性能更优异。表3进一步给出了低温还原峰(Peak 1)H₂消耗量占理论值的比例, Ni/ZrO₂, Ni/CeO₂及Ni/La₂O₂CO₃催化剂对应该比值分别为27%, 64%和94%, 即可还原的表面NiO浓度显著增加, 低温氧化还原性能随之增强。由此可见, 重整催化剂低温氧化还原能力增强, 重整反应产物中H₂浓度随之增大, 但也导致了可供随后SCR反应利用的HCs浓度的降低(见表2)。该特性使得耦合体系上NO_x还原温度窗口向低温移动, 最高NO_x转化率降低, 这清楚地表明了重整催化剂的氧化还原性能在重整-SCR组合体系净化NO_x中的关键作用。Ni/ZrO₂呈现出适中的氧化还原性能, 其催化十二烷重整后的产物中H₂及HC含量适中, 使得Ni/ZrO₂+Ag/Al₂O₃组合体系在柴油车典型的排气温度范围内表现出优异的NO_x净化效率。

3.4. 催化剂的稳定性

由表2可见, Ni基催化剂上*n*-C₁₂H₂₆重整过程中H₂产率随着反应时间的延长而有所降低, 这很可能与催化剂表面的积碳相关^[53]。为此, 将873 K温度下持续反应3 h后的各催化剂进行了TG分析, 结果见图5。Ni/Al₂O₃催化剂失重率高达21.57%, 据此算得平均积炭率约为0.072

g-C/(g-cat·h), 积炭现象严重。另外, 该催化剂催化*n*-C₁₂H₂₆重整产物中检测到了C₂H₄的生成(约0.15%), 而其它重整催化剂上则没有该产物的生成, 表明Al₂O₃表面的强酸性导致了重整制氢反应副产物C₂H₄的生成, 加剧了催化剂积炭^[46]。与此相比, ZrO₂, CeO₂和La₂O₂CO₃负载的Ni催化剂的失重率明显降低, 分别为9.58%, 8.24%和6.17%。由此可见, 重整催化剂的氧化还原性能不仅影响氢气的产率, 同时也是决定重整过程中积炭效应的重要因素, 强的氧化还原能力可有效抑制积炭发生, 与文献结果一致^[47,48]。另外Ni/La₂O₂CO₃上可发生反应La₂O₂CO₃ + C → La₂O₃ + 2CO, 促进了催化剂表面积炭的氧化去除, 有可能进一步抑制积炭^[51]。

鉴于Ni/ZrO₂+Ag/Al₂O₃较为理想的NO_x净化效果, 图6给出了该催化组合体系在重整-SCR反应过程中H₂浓度和NO_x转化率随时间的变化, 其中重整反应温度为773 K, NO_x还原温度为650 K。由图中可见, 在反应开始的2 h内重整反应产物中H₂浓度和NO_x转化率均有所下降, 但降幅不显著。随后的3 h反应中, H₂浓度保持在1%左右, NO_x转化率也基本维持在88%左右。随着反应时间延长, 10 h后H₂浓度明显下降至约0.2%, 随后缓慢下降。H₂浓度的降低导致了NO_x转化率的下降, 但其降幅远低于前者。反应进行24 h后, NO_x转化率可稳定在70%左右。连续反应24 h后Ni/ZrO₂样品的热重结果显示其失重率达16.5%, 存在明显的积炭现象, 表明其性能有待进一步改进。

4. 结论

载体性质显著影响了Ni基重整催化剂的氧化还原性能, 从而明显改变了其催化*n*-C₁₂H₂₆重整的反应产物中H₂及小分子HCs含量, 进而影响了燃油重整-SCR耦合体系的NO_x净化效果。Ni/ZrO₂催化*n*-C₁₂H₂₆重整产物中H₂及HCs浓度符合SCR反应所需的最佳比例范围(H₂ 1.1%, HC/NO_x = 7.5), 使得Ni/ZrO₂+Ag/Al₂O₃耦合体系在柴油车典型的排气温度范围内表现出良好的NO_x的净化效率。然而Ni基催化剂的积炭导致了其产氢性能降低, 从而影响了燃油重整-SCR组合体系净化NO_x的效率。
